Spatial Relations

- Distance relations
- Neighborhood relations
- Spatio-topological relations

Spatio-topological Relations

a disjoint b

a overlaps b

a contains b

Use Cases in Road Traffic

- Will vehicles collide in the nearby future?
- Do the sensors cover the bicycle lane during turning?

RQ: What to do when poses and/or boundaries are not known without fault?

- Pose errors, caused by sensors for example
- Fuzzy boundaries, caused by image segmentation for example

Probabilistic Geometric Objects

Model of a geometric object, with each point mapped to a probability value indicating occurrence of the geometric object at this point.

Model Pose Errors into Geometric Objects

Model Pose Errors into Geometric Objects

$$PGO(x, y) = \sum_{\tilde{x}=-x_{max}}^{x_{max}} \sum_{\tilde{y}=-y_{max}}^{y_{max}} p(\tilde{x}, \tilde{y}) \cdot GO(x - \tilde{x}, y - \tilde{y})$$

- $GO(x, y)$: Geometric Object
- $PGO(x, y)$: Probabilistic Geometric object
- $p(x, y)$: Discrete probability distribution

Known as **Convolution**: $PGO(x, y) = p(x, y) * GO(x, y)$

Performance Optimization: $PGO = \mathcal{F}^{-1}(\mathcal{F}(p) \cdot \mathcal{F}(GO))$

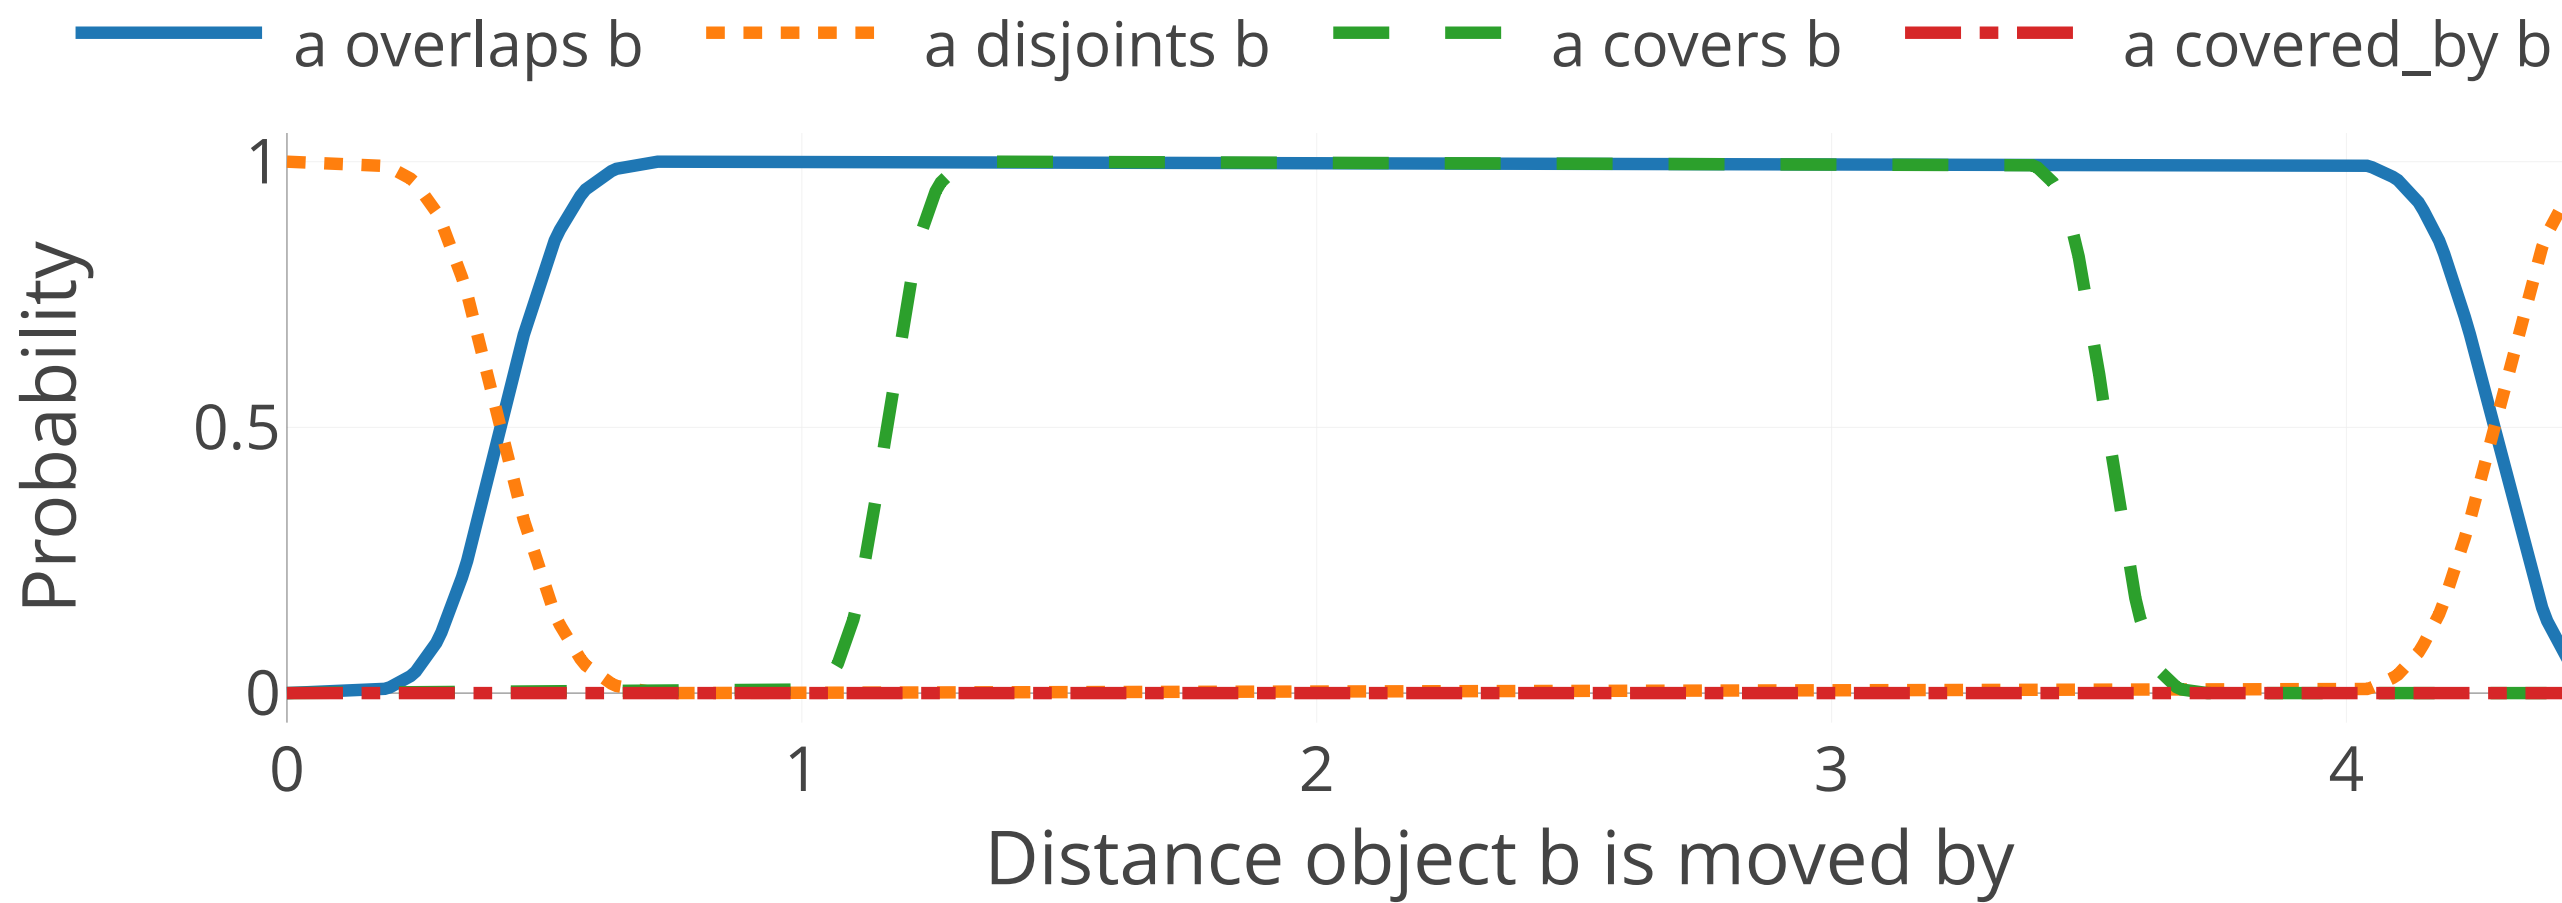

Example

Probabilistic Overlaps

- Probability of a and b overlapping at point $(x|y)$
 - $overlaps_{point}(a, b, (x, y)) = a(x, y) \cdot b(x, y)$
- Probability of a and b overlapping in at least one point in 2D plane
 - $overlaps(a, b) = \max_{(x,y) \in \mathbb{R}^2} a(x, y)b(x, y)$

Operator	Boolean Condition	Probabilistic Condition
Overlaps	$a \cap b \neq \emptyset$	$\max_{(x,y) \in \mathbb{R}^2} a(x,y)b(x,y)$
Disjoints	$a \cap b = \emptyset$	$\min_{(x,y) \in \mathbb{R}^2} 1 - a(x,y)b(x,y)$
Covers	$a \cap b = b$	$\{\max_{(x,y) \in a \cup b} a(x,y)b(x,y)\} \cdot \{1 - \max_{(x,y) \in b \setminus a} b(x,y)\}$
Covered_by	$a \cap b = a$	$\{\max_{(x,y) \in a \cup b} a(x,y)b(x,y)\} \cdot \{1 - \max_{(x,y) \in a \setminus b} a(x,y)\}$

Experiment with Carla Simulator

Setup of Experiment

- Discrete trajectories are 9m long with poses every 0.5m
- Pose Errors for future points in trajectory:
 - Std. deviation of 0 at presence
 - Std. deviation increases by 0.75 per meter into future along direction of motion
- Temporal monitoring:
 - $collision = \max(overlaps_i(red_i, blue_i))$ for $i = [0.5, 1, \dots, 9]$
- Evaluation happens every 12.5ms

Conclusion

- Boolean spatio-topological relations were generalized using probabilistics
- Applicability supported by experiment, though more experiments and evaluation would be beneficial
- Next step: Temporal monitoring of probabilistic spatial relations
